

Getting Started

Prerequisites

- PHP version 8.4.13
- PHP extensions : pdo_sqlite
- Package manager : Composer
- OS supported : Windows, Debian & Ubuntu

Configuration

To configure the application, you'll need to set up your environment variables.

1. Copy the example environment file:

```
cp .env.example .env
```

2. Open the `.env` file and edit the database variables to match your local setup. You can choose between SQLite, MySQL, or MariaDB by uncommenting the appropriate section.

Installation & Setup

After cloning the repository and configuring your `.env` file, run the following commands from the root of the project to get everything set up.

1. **Install PHP dependencies** using Composer:

```
composer install
```

2. **Update the autoloader** (optional, but good practice during development):

```
composer dump-autoload
```

3. **Run database migrations** to create the necessary tables:

```
php database/migrate.php
```

4. **(Optional) Seed the database** with initial mock data:

```
php database/seed.php
```
